AIVY: An AI-Powered Gamified Learning Platform Utilizing Agentic AI and Virtual Companions to Enhance Student Engagement and Personalized Education

By Anvith Shetty, Payal Niwane, Ritkriti Singh, Yash Mirge

I. Abstract

E-learning platforms have radically changed the world of education and made it more accessible to everyone. But along the way, these platforms continue to suffer from two core problems: low student engagement and the inflexibility of the traditional content delivery that basically ignores individual learners. On the one hand, gamification elements like points and leaderboards have gained immense popularity as a way of motivating students. However, they mostly encourage extrinsic, short, term engagement rather than deep, long, lasting learning. On the other hand, AI has made it possible to deliver adaptive content recommendation, but the majority of such systems only serve as passive recommendation engines rather than real, active pedagogical partners. This article presents AIVY, an AI, driven gamified learning platform that combines Agentic AI with the concept of a virtual pet companion to offer learners a highly personalized and intrinsically motivating educational experience. Developed with technologies such as React, FastAPI, MongoDB, and the OpenAI Agentic SDK coupled with Gemini, AIVY serves as a dynamic tutor that evaluates individual learner profiles, diagnoses learning deficiencies, and modifies teaching approaches on the fly. The main invention of the platform is the innovative use of a virtual pet whose health and happiness student's academic work are directly linked learning and practicing new skills is rewarded not only with task completion but also through your pets growth and acquisition of new rewards. Thus the students working towards the abstract educational targets becomes a source of real, emotionally charged i.e., meaningful results, helping thereby to establish learning habits and develop self, regulation capabilities. Early results indicate that the system is able to achieve user engagement and user perceived personalization that are much higher than with standard e, learning interfaces. The composition of the system, the approach to its realization and the preliminary results are presented in this paper. The article also discusses how AIVY relates to the trend of the synergy of AI and gamification for developing 21st, century skills.

II. Introduction

The rapid growth of digital learning has improved educational accessibility; however, sustaining learner engagement and delivering personalized instruction remain significant challenges. Many traditional e-learning systems rely on static content models that fail to adapt to individual performance and motivation, often leading to disengagement or inappropriate difficulty levels. Gamification has been widely adopted to enhance engagement by integrating elements such as points, badges, and leaderboards into learning environments. Studies indicate that gamification can improve behavioural engagement and, in certain contexts, learning outcomes [1], [2].

Nevertheless, its effectiveness largely depends on thoughtful design and contextual alignment [1]. Despite its motivational benefits, gamification alone does not ensure personalization. Uniform gamified systems may not address individual learner differences. Consequently, recent research emphasizes adaptive and personalized gamification approaches that tailor mechanics and learning pathways to user characteristics [1], [3].

Artificial Intelligence (AI) enables such personalization by analysing learner data—including accuracy, response time, and interaction history—to dynamically adjust content and feedback [4], [2]. The integration of AI with gamification facilitates both motivation and adaptive learning progression. However, much of the existing research focuses on classroom-scale implementations rather than practical single-user adaptive systems. To address this gap, this paper proposes AIVY, an AI-powered gamified learning platform that combines performance-based personalization with structured engagement mechanisms for individualized learning.

III. Literature Review

A. Gamification in Digital Learning

Gamification has been widely investigated as a mechanism to enhance engagement in educational contexts. Sailer and Homner [1] report that gamification positively influences motivational and behavioural outcomes, though effectiveness depends on design quality and contextual integration. Similarly, research in human–computer interaction shows that elements such as points, feedback systems, and progress tracking improve user interaction and persistence [2].

Grounded in self-determination theory, gamification supports intrinsic motivation by reinforcing autonomy, competence, and achievement. However, superficial implementations that merely overlay reward systems without pedagogical alignment may increase short-term participation without improving meaningful learning outcomes [1].

B. Adaptive and Personalized Gamification

To address the limitations of static gamification, researchers have proposed adaptive and personalized frameworks. Bennani et al. [5] emphasize the importance of learner modelling techniques that dynamically adjust game mechanics based on user traits and

performance data. Personalized gamification approaches tailor rewards, feedback, and difficulty progression to individual learners, yielding stronger engagement and satisfaction compared to uniform designs [3].

Further studies indicate that gamification is most effective when game elements are aligned with cognitive progress rather than mere participation metrics [4]. These findings highlight the need for adaptive intelligence within gamified learning environments.

C. Artificial Intelligence in Adaptive Learning

Artificial Intelligence enables dynamic personalization by analysing learner data to adjust content sequences, difficulty levels, and feedback mechanisms [6], [7]. AI-driven adaptive systems aim to maintain learners within an optimal challenge range, minimizing frustration and disengagement.

The integration of AI with gamification further enhances personalization. AI can dynamically modify reward structures, progression models, and feedback intensity based on real-time learner behaviour [5], [8], creating an adaptive ecosystem where engagement strategies evolve alongside performance.

D. Research Gaps

Despite strong evidence supporting gamification and AI-based personalization independently, fully integrated architectures remain limited. Key gaps include:

- Limited real-time AI adaptation within gamified systems
- Insufficient focus on single-user adaptive models
- Lack of standardized modular frameworks integrating personalization and gamification engines

Most existing studies emphasize classroom-scale interventions rather than practical individual learning systems.

E. Positioning of AIVY

Building on adaptive gamification research [5], motivational meta-analyses [1], and AI-driven personalization studies [6], AIVY proposes a modular architecture that integrates performance-based adaptation, dynamic difficulty adjustment, structured gamification, and real-time personalization. Unlike traditional gamified platforms, AIVY directly aligns reward mechanisms with cognitive performance metrics, ensuring that motivation supports measurable learning progression.

IV. System Design and Architecture

A. System Overview

AIVY is a single-user AI-powered gamified learning platform designed to enhance student engagement through adaptive personalization and performance-based rewards. The system dynamically adjusts content difficulty based on user performance while maintaining motivation using structured gamification elements.

The architecture follows a modular three-layer design:

1. Presentation Layer
2. Application Layer
3. Data Layer

This structure enables real-time adaptation, efficient data processing, and scalable future expansion.

B. Overall Architecture

The system architecture consists of a user interface connected to an intelligent backend responsible for personalization and gamification logic, supported by a structured data storage layer.

Architecture Flow:

User → Presentation Layer → Application Layer (AI + Gamification) → Data Layer

C. Presentation Layer

The Presentation Layer provides an interactive interface through which the user accesses learning content and tracks progress.

Key features include:

- Personalized dashboard (XP, level, progress)
- Quiz and challenge interface
- Achievement and badge display
- Performance summary and streak tracking

This layer ensures usability and responsiveness, enabling seamless interaction with backend services.

D. Application Layer

The Application Layer is the core component of AIVY and consists of two integrated modules:

1. AI Personalization Engine
2. Gamification Engine

These modules work together to ensure adaptive learning and sustained engagement.

1) AI Personalization Engine

The AI engine analyzes user performance metrics to dynamically adjust content difficulty.

The system evaluates:

- Accuracy (A)
- Response Time (T)
- Historical Performance (H)

The next difficulty level is determined as:

$$D_{next} = f(A, T, H)$$

Where:

- High accuracy and stable response time increase difficulty.
- Low accuracy decreases difficulty.
- Consistent performance maintains level stability.

This adaptive mechanism ensures the learner remains within an optimal challenge range, preventing disengagement due to excessive difficulty or monotony.

The personalization process follows:

1. User completes activity
2. Performance metrics recorded
3. AI evaluates learning state
4. Difficulty recalibrated
5. Next content recommended

2) Gamification Engine

The Gamification Engine enhances motivation by integrating structured reward mechanisms.

Implemented elements include:

- Experience Points (XP)
- Level progression
- Achievement badges
- Streak rewards

XP is calculated as:

$$XP = BaseScore + SpeedBonus + StreakBonus$$

Where:

- BaseScore reflects correctness.
- SpeedBonus rewards quicker completion.
- StreakBonus incentivizes consistent performance.

The reward system is performance-driven, ensuring that motivation is directly aligned with learning outcomes rather than passive participation.

E. Content Management

Educational content is categorized into three levels:

- Beginner
- Intermediate
- Advanced

Each module contains instructional material and assessment activities tagged by difficulty. The AI engine dynamically selects appropriate content based on user progression.

F. Data Layer

The Data Layer stores:

- User profile data
- Performance metrics
- Learning history
- XP and achievement records
- Difficulty progression

Historical data supports long-term personalization and continuous system optimization.

The system may utilize relational or NoSQL databases depending on deployment requirements.

G. System Workflow

The operational workflow of AIVY is summarized below:

1. User logs in.
2. Profile data is retrieved.
3. Personalized content is assigned.
4. User completes gamified tasks.
5. Performance data is recorded.
6. Difficulty level is recalculated.

7. XP and achievements are updated.
8. Dashboard reflects updated progress.

V. Conclusion

This paper presented AIVY, a single-user AI-powered gamified learning platform designed to enhance student engagement and deliver personalized educational experiences. The system integrates an adaptive AI engine with structured gamification mechanisms to dynamically adjust learning difficulty while maintaining user motivation. The proposed architecture combines performance-based personalization with reward-driven engagement strategies. By continuously analysing user accuracy, response time, and historical performance, AIVY ensures that learners remain within an optimal challenge range. The integration of experience points, level progression, and achievement badges further reinforces consistent participation and sustained interaction.
